

Due date: Monday September 28 at 11:59pm

Your task: In this assignment, you will practice using jQuery, jQuery UI widgets, and JavaScript objects to dynamically create and insert content into an existing HTML page.

Requirements:

1. Do **not** modify existing id or class attributes in the HTML file.
2. Remove the following content from the HTML file:
 - a. The text in the username
 - b. The text displaying the revenue amount
 - c. The text displaying the number of customers
 - d. The text displaying the number of orders
 - e. The text displaying the number of issues
 - f. In the Overview section, remove the text displaying the revenue amount.
 - g. In the Sales summary section, remove **all rows** within the `<tbody>` tag
 - h. In the activity section, remove **all list items** within the `<ul>` tag
 - i. In the recent customers section, remove **all rows** within the `<tbody>` tag
 - j. In the system status section, remove **all list items** within the `<ul>` tag
 - k. In the notifications section, remove **all list items** within the `<ol>` tag
 - l. In the notifications section, remove the number of notifications from the message: "You have **3** new notifications"
 - m. In the tasks section, remove **all list items** within the `<ul>` tag

NOTE: A branch must be created addressing the removal of HTML elements. Once you finish removing elements commit and merge these updated to the main branch. This is the first PR.

3. In your JS file, write the necessary functions and code to build the required text/html on -the-fly. Each of the elements removed from the HTML file must

eventually be replaced dynamically using data from JS objects provided in the JS file. To do so, identify the id or class attribute where the content should be inserted. Use JS or jQuery commands to select the appropriate elements. Then, insert the newly created text/element inside the selected HTML element, just as we did in the last lab.

4. In your JS file, use jQuery UI to transform HTML elements into specified widgets.
 - a. Convert **all** HTML buttons into jQuery Button Widgets.
 - b. Convert the element with id dashboardTabs into a jQuery UI Tabs Widget.
 - c. Convert the element with id customerDialog a jQuery Dialog Widget.

This widget must use the following properties:

```
autoOpen: false,
modal: true,
width: 450,
buttons: {
  "Create Customer": function () {
    var name = $("#customerName").val();
    var email = $("#customerEmail").val();
    if (!name || !email) {
      alert(
        "Please enter a name and email."
      );
      return;
    }

    alert("Customer created: " + name);
    $(this).dialog("close");
  },
  "Cancel": function () {
    $(this).dialog("close");
  }
}
```

- d. Convert the element with id accordion into a jQuery Accordion Widget.

This widget must use the following properties:

```
collapsible: true,  
heightStyle: "content"
```

- e. Add a jQuery event listener to the element with id newCustomerButton. When the button is clicked, the event listener must open the jQuery dialog with id customerDialog.
- f. Convert the element with id customerDate into a jQuery Datepicker Widget. You will find this field inside the customer dialog box.
- g. FYI: The following buttons are not functional: Dashboard, Customers, Reports.

NOTE: Another branch must be created addressing the addition of JS updates. Once you finish implementation and testing, commit and merge these updates to the main branch. This is the second PR.

Submission: Your solution must be hosted in GitHub, and **your repository should contain multiple commits demonstrating your progress throughout the assignment.** Use the Brightspace submission tools to submit a single text file containing the link to your GitHub repository.

Sample Output: Dialog box closed
